3	Analysis of site status evaluation variables	3
4	Analysis of stream condition variables	8
5	Analysis of stream condition variables correcting for population size	10
6	Analysis of quantitative variables	11

### 1 Preliminaries

This document presents analysis of a GRTS survey design for a linear resource. The linear resource used in the analysis is streams in the Upper Wabash basin in Indiana. The analysis will include calculation of three types of population estimates: (1) estimation of proportion and size (length of streams) for site evaluation status categorical variables; (2) estimation of proportion and size for stream condition categorical variables; and (3) estimation of the cumulative distribution function (CDF) and percentiles for quantitative variables. Testing for difference between CDFs from subpopulations also will be presented.

The initial step is to use the library function to load the spsurvey package. After the package is loaded, a message is printed to the R console indicating that the spsurvey package was loaded successfully.

Load the spsurvey package

```
> # Load the spsurvey package
> library(spsurvey)
>
```

Version 3.1 of the spsurvey package was loaded successfully.

## 2 Load the survey design and analytical variables data set

The next step is to load the data set, which includes both survey design variables and analytical variables. The data function is used to load the data set and assign it to a data frame named IN\_streams. The nrow function is used to determine the number of rows in the IN\_streams data frame, and the resulting value is assigned to an object named nr. Finally, the initial six lines and the final six lines in the IN\_streams data frame are printed using the head and tail functions, respectively.

Load the survey design and analytical variables data set

```
> # Load the data set and determine the number of rows in the data frame
> data(IN_streams)
> nr <- nrow(IN_streams)
>
```

Display the initial six lines in the data file.

> # Display the initial six lines in the data file
> head(IN\_streams)

```

The sample of streams in Indiana is displayed in Figure 1. The sample sites for each Strahler order are displayed using a unique color.

# 3 Analysis of site status evaluation variables

The first analysis that will be examined is calculation of extent estimates for site status evaluation variables. Extent is measured both by the proportion of the resource in status evaluation categories and by size of the resource in each category. For a linear resource like streams, size refers to the length of streams in a category. For calculating extent estimates (and for all of the analyses we will consider), the survey design weights are incorporated into the calculation process. Two site status variables will be examined: (1) status, which classifies streams into seven evaluation categories and (2) TNT, which classifies streams as either "Target" or "NonTarget". The table and addmargins functions are used to create tables displaying the count for each code (level) of the two status variables.

> addmargins(table(IN\_streams\$Status))

## Indiana Stream Sites Color-Coded by Strahler Order

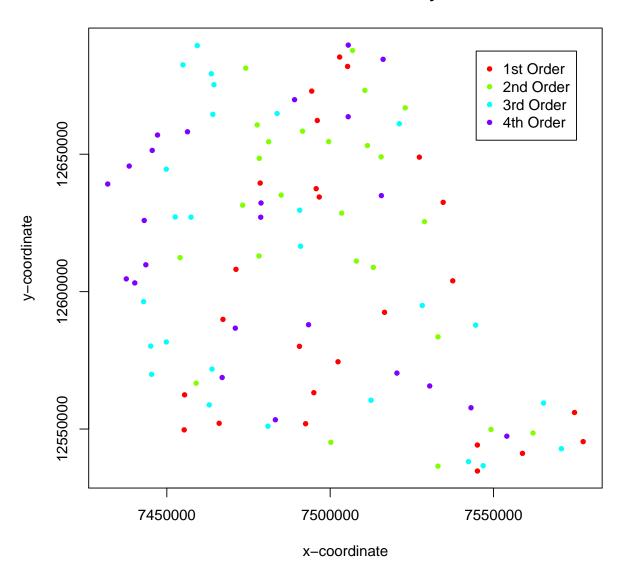

Figure 1: Location of stream sample sites in Indiana color-coded by Strahler order.

A table displaying the number of values for each level of the status variable follows:

Chemistry_Only	Landowner_Denial	${\tt NonTarget}$	Physical_Barrier
14	19	9	7
Sampled	Target_Not_Sampled	Unknown	Sum
48	2	1	100

> addmargins(table(IN\_streams\$TNT))

A table displaying the number of values for each level of the TNT variable follows:

NonTarget	Target	Sum
10	90	100

The cat analysis function in the spsurvey package will be used to calculate extent estimates. Four data frames constitute the primary input to the cat.analysis function. The first column (variable) in the four data frames provides the unique identifier (site ID) for each sample site and is used to connect records among the data frames. The siteID variable in the IN\_streams data frame is assigned to the site ID variable in the data frames. The four data frames that will be created are named as follows: sites, subpop, design, and data.cat. The sites data frame identifies sites to use in the analysis and contains two variables: (1) siteID - site ID values and (2) Use - a logical vector indicating which sites to use in the analysis. The rep (repeat) function is used to assign the value TRUE to each element of the Use variable. Recall that nr is an object containing the number of rows in the IN\_streams data frame. The subpop data frame defines populations and, optionally, subpopulations for which estimates are desired. Unlike the sites and design data frames, the subpop data frame can contain an arbitrary number of columns. The first variable in the subpop data frame identifies site ID values and each subsequent variable identifies a type of population, where the variable name is used to identify type. A type variable identifies each site with a character value. If the number of unique values for a type variable is greater than one, then the set of values represent subpopulations of that type. When a type variable consists of a single unique value, then the type does not contain subpopulations. For this analysis, the subpop data frame contains three variables: (1) siteID - site ID values, (2) Upper\_Wabash - which will be used to calculate estimates for all of the sample sites combined, and (3) Strahler\_Order - which will be used to calculate estimates for each Strahler order individually. The Strahler\_order variable in the IN\_streams data frame is assigned to the Strahler\_Order variable in the subpop data frame. The design data frame consists of survey design variables. For the analysis under consideration, the design data frame contains the following variables: (1) siteID - site ID values; (2) wgt - final, adjusted, survey design weights; (3) xcoord - x-coordinates for location; and (4) ycoord - y-coordinates for location. The wgt, xcoord, and ycoord variables in the design data frame are assigned values using variables with the same names in the IN\_streams data frame. Like the subpop data frame, the data.cat data frame can contain an arbitrary number of columns. The first variable in the data.cat data frame identifies site ID values and each subsequent variable identifies a response variable. The two response variables are Status and Target\_NonTarget, which are assigned the status and TNT variables, respectively, in the IN\_streams data frame. Missing data (NA) is allowed for the response variables, which are the only variables in the input data frames for which NA values are allowed.

Create the sites data frame.

```
> sites <- data.frame(siteID=IN_streams$siteID,
+ Use=rep(TRUE, nr))</pre>
```

Create the subpop data frame.

Create the design data frame.

Create the data.cat data frame.

Use the cat.analysis function to calculate extent estimates for the site status evaluation variables.

```
> # Calculate extent estimates for the site status evaluation variables
> Extent_Estimates <- cat.analysis(sites, subpop, design, data.cat)
>
```

The extent estimates for all basins combined are displayed using the print function. The object produced by cat.analysis is a data frame containing thirteen columns. The first five columns identify the population (Type), subpopulation (Subpopulation), response variable (Indicator), levels of the response variable (Category), and number of values in a category (NResp). A category labeled "Total" is included for each combination of population, subpopulation, and response variable. The next four columns in the data frame provide results

for the proportion estimates: the proportion estimate (Estimate.P), standard error of the estimate (StdError.P), lower confidence bound (LCB95Pct.P), and upper confidence bound (UCB95Pct.P). Argument conf for cat.analysis allows control of the confidence bound level. The default value for conf is 95, hence the column names for confidence bounds contain the value 95. Supplying a different value to the conf argument will be reflected in the confidence bound names. Confidence bounds are obtained using the standard error and the Normal distribution multiplier corresponding to the confidence level. The final four columns in the data frame provide results for the size (units) estimates: the units estimate (Estimate.U), standard error of the estimate (StdError.U), lower confidence bound (LCB95Pct.U), and upper confidence bound (UCB95Pct.U).

## > # Print the extent estimates for all basins combined

> print(Extent\_Estimates[c(1:8, 32:34),])

```

The write.csv function is used to store the extent estimates as a comma-separated value (csv) file. Files in csv format can be read by programs such as Microsoft Excel.

```
> write.csv(Extent_Estimates, file="Extent_Estimates.csv", sep=",",
+ row.names=FALSE)
```

# 4 Analysis of stream condition variables

The second analysis that will be examined is estimating resource proportion and size for stream condition variables. Two stream condition variables will be examined: (1) IBLStatus, which classifies streams by IBI (index of biotic integrity) status categories and (2) QHELStatus, which classifies streams by QHEI (qualitative habitat evaluation index) status categories. The table and addmargins functions are used to create tables displaying the count for each level of the two stream condition variables.

```
> addmargins(table(IN_streams$IBI_Status))
```

A table displaying the number of values for each level of the IBI status variable follows:

```
Impaired Not_Impaired Sum
12 36 48
```

> addmargins(table(IN\_streams\$QHEI\_Status))

A table displaying the number of values for each level of the QHEI status variable follows:

As for extent estimates, the cat.analysis function will be used to calculate condition estimates. The sites data frame for this analysis differs from the one used to calculate extent estimates. The Use logical variables in sites is set equal to the value "Sampled", so that only sampled sites are used in the analysis. The subpop and design data frames created in the prior analysis can be reused for this analysis. The data cat data frame contains the two stream condition variables: IBLStatus and QHELStatus. Variables IBLStatus and QHELStatus in the IN\_streams data frame are assigned to IBLStatus and QHELStatus, respectively.

Create the sites data frame.

Create the data.cat data frame.

Use the cat.analysis function to calculate estimates for the stream condition variables.

```
> # Calculate estimates for the categorical variables
> Condition_Estimates <- cat.analysis(sites, subpop, design, data.cat)
>
```

Print the stream condition estimates for all sites combined.

```
> # Print the condition estimates for all basins combined
> print(Condition_Estimates[c(1:3, 16:18),])
```

```

# 5 Analysis of stream condition variables correcting for population size

The frame is a data structure containing spatial location data in addition to other attributes regarding a resource of interest and is used to create a survey design. A frame often takes the form of a shapefile. The frame can be used to obtain size values (e.g., length of streams) for the populations and subpopulations examined in an analysis. Examination of the Estimates. U column in the Condition\_Estimates data frame produced by cat.analysis reveals that the estimated Total value for both condition variables and each combination of population value and subpopulation value does not sum to the corresponding frame size value. For example, the Total entry in the Estimate. U column for the IBL status variable, population "Upper\_Wabash" and subpopulation "Upper Wabash" is 3,417 kilometers (rounded to a whole number). The corresponding frame size value is 7,358 kilometers. The popsize (population size) argument to cat. analysis provides a mechanism for forcing the Total category to equal a desired value. First, the c (combine) function is used to create a named vector of frame size values for each basin. Output from the c function is assigned to an object named framesize. The popsize argument is a list, which is a particular type of R object. The popsize list must include an entry for each population type included in the subpop data frame, i.e., Upper\_Wabash and Strahler\_Order for this analysis. The sum function applied to framesize is assigned to the Upper\_Wabash entry in the popsize list. Recall that the Strahler order population type contains subpopulations, i.e., Strahler order categories. When a population type contains subpopulations, the entry in the population is a list. The as list function is applied to framesize, and the result is assigned to the Strahler\_Order entry in the popsize

Assign frame size values.

```
> framesize <- c("1"=4514.450, "2"=1443.260, "3"=740.146, "4"=660.294)
```

Use the cat.analysis function to calculate estimates for the stream condition variables.

```
> Condition_Estimates_popsize <- cat.analysis(sites, subpop, design, data.cat,
+ popsize=list(Upper_Wabash=sum(framesize),
+ Strahler_Order=as.list(framesize)))</pre>
```

Print the stream condition estimates for all sites combined.

- > # Print the stream condition estimates for all sites combined
  > print(Condition\_Estimates\_popsize[c(1:3, 16:18),])
- Type Subpopulation Indicator Category NResp Estimate.P Upper Wabash IBI\_Status 12 27.66052 Upper\_Wabash Impaired 36 72.33948 Upper\_Wabash Upper Wabash IBI\_Status Not\_Impaired Upper\_Wabash Upper Wabash IBI\_Status Total 48 100.00000 16 Upper\_Wabash Upper Wabash QHEI\_Status Impaired 14 40.90216 17 Upper\_Wabash Upper Wabash QHEI\_Status Not\_Impaired 34 59.09784 Upper Wabash QHEI\_Status 18 Upper\_Wabash Total 48 100.00000 StdError.P LCB95Pct.P UCB95Pct.P Estimate.U StdError.U LCB95Pct.U UCB95Pct.U 6.611920 14.70139 40.61964 2035.302 486.5150 1081.750 1 2988.854 2 59.38036 85.29861 4369.296 6.611920 5322.848 486.5150 6276.400 3 7358.150 NANANANANA NA16 8.383366 24.47106 57.33325 616.8607 1800.618 3009.642 4218.667 17 8.383366 42.66675 75.52894 4348.508 616.8607 3139.483 5557.532 18 NA NA NA7358.150 NA NA NA

Use the write csv function to write the condition estimates as a csv file.

> write.csv(Condition\_Estimates\_popsize, file="Condition\_Estimates\_popsize.csv")

## 6 Analysis of quantitative variables

The third analysis that will be examined is estimating the CDF and percentiles for quantitative variables. Two quantitative variables will be examined: (1) IBLScore - IBI score and (2) QHELScore - QHEI score. The summary function is used to summarize the data structure of the two quantitative variables.

> summary(IN\_streams\$IBI\_Score)

>

Summarize the data structure of the IBI score variable:

```
Min. 1st Qu. Median Mean 3rd Qu. Max. NA's 0.00 31.50 36.00 36.12 42.00 54.00 52
```

> summary(IN\_streams\$QHEI\_Score)

Summarize the data structure of the QHEI score variable:

```
Min. 1st Qu. Median Mean 3rd Qu. Max. NA's 25.00 47.75 60.00 59.65 71.25 87.00 52
```

The cont.analysis function will be used to calculate estimates for quantitative variables. Input to the cont.analysis function is the same as input for the cat.analysis function except that the data frame containing response variables is named cont.data rather than cat.data. The sites, subpop, and design data frames created in the analysis of stream condition variables can be reused for this analysis. The data.cont data frome contains the two quantitative variables: IBL\_Score and QHEL\_Score, which contain the numeric scores for the IBI and QHEI variables, respectively. Variables IBL\_Score and QHEL\_Score in the IN\_streams data frame are assigned to IBL\_Score and QHEL\_Score, respectively. The popsize argument is included in the call to cont.analysis.

Create the data.cont data frame.

Use the cont.analysis function to calculate CDF and percentile estimates for the quantitative variables.

```
> CDF_Estimates <- cont.analysis(sites, subpop, design, data.cont,
+ popsize=list(Upper_Wabash=sum(framesize),
+ Strahler_Order=as.list(framesize)))</pre>
```

The object produced by cont.analysis is a list containing two objects: (1) CDF, a data frame containing the CDF estimates and (2) Pct, a data frame containing percentile estimates plus estimates of population values for mean, variance, and standard deviation. Format for the CDF data frame is analogous to the data frame produced by cat.analysis. For the CDF data frame, however, the fourth column is labeled Value and contains the value at which the CDF was evaluated. Unlike the data frames produced by the other analysis functions we have examined, the Pct data frame contains only nine columns since there is a single set of estimates rather than two sets of estimates. In addition, the fourth column is labeled Statistic and identifies either a percentile or the mean, variance, or standard deviation. Finally, since percentile estimates are obtained by inverting the CDF estimate, the percentile estimates do not have a standard error value associated with them.

Use the write.csv function to write the CDF estimates as a csv file.

```
> write.csv(CDF_Estimates$CDF, file="CDF_Estimates.csv")
```

The cont.cdfplot function in spsurvey can be used to produce a PDF file containing plots of the CDF estimates. The primary arguments to cont.cdfplot are a character string containing a name for the PDF file and the CDF data frame in the CDF\_Estimates object.

Produce a PDF file containing plots of the CDF estimates.

```
> cont.cdfplot("CDF_Estimates.pdf", CDF_Estimates$CDF)
>
```

Print the percentile estimates for IBI score for all sites combined.

> # Print the percentile estimates for IBI score for all sites combined
> print(CDF\_Estimates\$Pct[1:10,])

```

```

The cont.cdftest function in spsurvey can be used to test for statistical difference between the CDFs from subpopulations. For this analysis we will test for statistical difference between the CDFs for the four Strahler order categories. The cont.cdftest function will test all possible pairs of Strahler order categories. Arguments to cont.cdftest are the same as arguments to cont.analysis. Since we are interested only in testing among Strahler order categories, the subpop data frame is subsetted to include only the siteID and Strahler\_Order variables. Note that the popsize argument was modified from prior examples to include only the entry for Strahler\_Order.

```
> CDF_Tests <- cont.cdftest(sites, subpop[,c(1,3)], design, data.cont,
+ popsize=list(Strahler_Order=as.list(framesize)))</pre>
```

During execution of the program, a warning message was generated. The warning message is stored in a data frame named 'warn.df'. Enter the following command to view the warning message: warnprnt()

The print function is used to display results for IBI score of the statistical tests for difference between CDFs for Strahler order categories. The object produced by cont.cdftest is a data frame containing eight columns. The first column (Type) identifies the population. The second and third columns (Subpopulation\_1 and Subpopulation\_2) identify the subpopulations. The fourth column (Indicator) identifies the response variable. Column five contains values of the test statistic. Six test statistics are available, and the default statistic is an F-distribution version of the Wald statistic, which is identified in the data frame as "Wald-F". The default statistic is used in this analysis. For further information about the test statistics see the help file for the cdf.test function in spsurvey, which includes a reference for the test for differences in CDFs. Columns six and seven (Degrees\_of\_Freedom\_1 and Degrees\_of\_Freedom\_2) provide the numerator and denominator degrees of freedom for the Wald test. The final column (p\_Value) provides the p-value for the test.

>

Use the write.csv function to write CDF test results as a csv file.

```
> # Write CDF test results as a csv file
> write.csv(CDF_Tests, file="CDF_Tests.csv")
>
```
